**UNIVERSITY  
OF ALBERTA**

# Outline

- Introduction
- Dynamic Programming Approach
- PTAS
- Conclusion

# Motivation & Application

- Initiated from the Integrated Stockpile Evaluation (ISE) program which tests nuclear weapons periodically.
- Extend to the model where the machines need to be **calibrated periodically** to ensure high-quality products
  - Robotics
  - Digital cameras
  - ...

# Formulation

- A set  $J$  of  $n$  jobs, where each job  $j \in J$  has
  - a release time  $r_j$
  - a deadline  $d_j$
  - a processing time  $p_j = 1$
- $m$  identical parallel machines
  - a machine must be **calibrated** before it runs a job
  - calibrating a machine is **instantaneous** in the ideal model
  - the calibration remains valid for a time period of **length  $T$**

# Objective

- Minimize **the number of calibrations**  
(ensuring completes all jobs before their deadlines)
- A feasible solution includes:
  - Schedule of calibrations (when to start a calibration)
  - Schedule of jobs (when and on which machine to start a job)

# Results Summary

Algorithm	Approximation Ratio	Time Complexity	Remark
Our DP Approach 1	1	$O(n^{8+6m})$	$m$ is constant
Our DP Approach 2	1	$O(n^8 m^{3T})$	$T$ is constant
Our PTAS	$1+\epsilon$	$O(n^{17+18\lceil 1/\epsilon \rceil})$	Both $m, T$ are input
Bender et al.	2	$Poly(n, m)$	Lazy-binning approach

# Earliest-Deadline-First Scheduling

- Sort the jobs by non-decreasing order of their **deadlines**, and non-decreasing order of release times if they have the same deadline.
- Index jobs from 1 to  $n$  after sorting.
- Once the schedule of calibrations is fixed:
  - consider each time slot  $t$ , i.e. time interval  $(t - 1, t]$
  - the job with smallest index has the highest priority

# Earliest-Deadline-First Scheduling

**Lemma 1 (EDF).** *There exists an optimal schedule such that for any two jobs  $i, j$  with  $i < j$ , if  $r_i \leq t_j$  then  $t_i \leq t_j$ .*

(where  $t_i, t_j$  are the corresponding starting times of job  $i$  and  $j$ )

The value  $(i - t_i)^2 + (j - t_j)^2$  strictly decrease after swapping

$\Rightarrow$  Every optimal schedule can be transformed into another optimal solution following EDF after a finite number of the swapping process

# Reduce the number of useful time slots

## **Definition 2.**

Let  $\Psi = \bigcup_{j \in J, s \in [0, n]} \{d_j - s\}$ ,  $\Phi = \bigcup_{j \in J, t \in \Psi, s \in [0, n]} \{r_j + s, t + s\}$  and  $\Phi(j) = \{t \mid r_j < t \leq d_j, t \in \Phi\}, \forall j \in J$ .

$|\Psi| = O(n^2)$  and  $|\Phi| = O(n^2)$

**Lemma 3.** [1] *There always exists an optimal schedule such that*

- I. *each calibration starts at a time in  $\Psi$ .*
- II.  *$\forall j \in J$ , job  $j$  finishes at a time in  $\Phi(j)$ .*

# Vector Representation of Calibrations

Mark the calibrations on each machine that cover time slot  $t$  by

$$\gamma = \langle \gamma_1, \gamma_2, \dots, \gamma_m \rangle$$

where  $\gamma_k \in \{NUL\} \cup (\Psi \cap [t - T, t))$  indicates the starting time of the calibration on machine  $k$ .

$$\Gamma(t) = \{ \langle \gamma_1, \gamma_2, \dots, \gamma_m \rangle \mid \gamma_k \in \{NUL\} \cup (\Psi \cap [t - T, t)), \forall k \in [1, m] \}$$

to be the set of all possible vectors, with respect to time slot  $t$ .

We define operator  $<$  (or  $\leq, >, \geq$ , analogously) to be  $\beta = (\lambda < x)$  where  $\beta_k = \lambda_k$  if  $\lambda_k \neq NUL, \lambda_k < x$  and otherwise  $\beta_k = NUL$ .

# Observation

**Definition 4.** Let  $J(j, t_1, t_2), \forall j \in J$  be the subset of jobs whose index is at most  $j$  and release time is between  $t_1$  and  $t_2$ ,  
i.e.,  $J(j, t_1, t_2) = \{i \mid i \leq j, r_i \in [t_1, t_2), i \in J\}$

If jobs  $J(j, t_1, t_2)$  are only scheduled during  $[t_1, t_2)$ , and job  $j$  is scheduled at time slot  $t$  :

- $J(j - 1, t_1, t)$  by EDF  $\Rightarrow$  must be scheduled during  $[t_1, t)$
- $J(j - 1, t, t_2)$  by release time  $\Rightarrow$  must be scheduled during  $[t, t_2)$

# Dynamic Programming States

**Definition 5.** Let  $f(j, t_1, t_2, q, \mathbf{u}, \mathbf{v})$  be the minimum number of calibrations to schedule jobs  $J(j, t_1, t_2)$  on  $m$  machines, where  $\mathbf{u} = \langle u_1, u_2, \dots, u_m \rangle$ ,  $\mathbf{u} - T \in \Gamma(t_1)$ ,  $\mathbf{v} = \langle v_1, v_2, \dots, v_m \rangle \in \Gamma(t_2)$ ,  $t_1 \in \Phi$ ,  $t_2 \in \Phi$ ,  $q \in [0, m]$  on the condition that

- jobs  $J(j, t_1, t_2)$  are **only** scheduled during time interval  $[t_1, t_2)$ .
- time intervals  $[t_1, u_k)$  and  $[v_k, t_2)$  have already been calibrated on machine  $k$ ,  $\forall k \in [1, m]$ .
- $q$  other jobs (not from  $J(j, t_1, t_2)$ ) have already been assigned to time slot  $t_2$ .

# Dynamic Programming Transitions

# Dynamic Programming Transitions

Let  $\delta(\lambda) = \sum_{\lambda_k \neq NUL, k \in [1, m]} 1$  on vector  $\lambda$ .

Then  $f(j, t_1, t_2, q, \mathbf{u}, \mathbf{v}) =$

$$\min_{t \in \Phi(j) \cap (t_1, t_2]} \begin{cases} \infty & , \text{if } t = t_2, q = m \\ f(j - 1, t_1, t_2, q + 1, \mathbf{u}, \mathbf{v}) & , \text{if } t = t_2, 0 < q < m \\ f(j - 1, t_1, t, 1, \mathbf{u}, \mathbf{v}') \\ \min_{cond.} + f(j - 1, t, t_2, q, \mathbf{u}', \mathbf{v}) & , \text{if } t < t_2 \text{ or } q = 0 \\ + \delta(\mathbf{x}) \end{cases}$$

where *cond.* represents  $\mathbf{x} \in \Gamma(t)$ ,  $\mathbf{y} = \mathbf{x} + T$ ,  $\mathbf{u}' = \max\{\mathbf{y}, \mathbf{u} \geq t\}$ ,  
 $\mathbf{v}' = \min\{\mathbf{x}, \mathbf{v} < t\}$

# Time Complexity

- The dynamic program has table size  $O(n^2|\Phi|^2|\Psi|^{2m})$ .
- Constructing the solution from the sub-problems takes  $O(|\Phi||\Psi|^m)$  steps.
- In total, the running time is  $O(n^2|\Phi|^3|\Psi|^{3m}) = O(n^{8+6m})$ .
- When  $m$  is constant, our dynamic programming approach has polynomial running time.

# Improve the Vector Representation

We only need to distinguish calibrations by their starting time.

Mark the **numbers of calibrations** distinguished by the number of remaining time slots that cover time slot  $t$  by

$$c_t = \langle c_{t,1}, c_{t,2}, \dots, c_{t,T} \rangle$$

where  $c_{t,k} \in \{0, 1, 2, \dots, m\}$  indicates the number of calibrations that makes the machine available at time slot  $t, t + 1, \dots, t + k - 1$ .

Let  $C(t) = \{ \langle c_{t,1}, c_{t,2}, \dots, c_{t,T} \rangle \mid c_{t,k} \in \{0, 1, 2, \dots, m\}, \forall k \in [1, T] \wedge \sum_{k=1}^T c_{t,k} \leq m \}$

be the set of all possible vectors, with respect to time slot  $t$ .

# Modified Dynamic Programming States

**Definition 9.** We define  $f(j, t_1, t_2, q, c_{t_1}, c_{t_2})$  to be the minimum number of calibrations to schedule jobs  $J(j, t_1, t_2)$  on  $m$  machines where  $c_{t_1} \in C(t_1)$ ,  $c_{t_2} \in C(t_2)$ ,  $t_1 \in \Phi$ ,  $t_2 \in \Phi$ ,  $q \in [0, m]$  on the condition that

- jobs  $J(j, t_1, t_2)$  are only scheduled during time interval  $[t_1, t_2)$ .
- machines have already been calibrated according to  $c_{t_1}$  and  $c_{t_2}$ .
- $q$  other jobs (not from  $J(j, t_1, t_2)$ ) have already been assigned to time slot  $t_2$ .

# Dynamic Programming Transitions

$$f(j, t_1, t_2, q, \mathbf{c}_{t_1}, \mathbf{c}_{t_2}) = \min_{t \in \Phi(j) \cap (t_1, t_2]} \begin{cases} \infty & , \text{if } t = t_2, q = m \\ f(j - 1, t_1, t_2, q + 1, \mathbf{c}_{t_1}, \mathbf{c}_{t_2}) & , \text{if } t = t_2, 0 < q < m \\ \sum_{k=1}^T c_{t,k} & , \text{if } t < t_2 \text{ or } q = 0 \\ \min_{\text{cond.}} + f(j - 1, t_1, t, 1, \mathbf{c}_{t_1}, \dot{\mathbf{c}}_t) & \\ \quad + f(j - 1, t, t_2, q, \ddot{\mathbf{c}}_t, \mathbf{c}_{t_2}) & \end{cases}$$

Where *cond.* stands for  $\dot{\mathbf{c}}_t = \max\{\iota(\mathbf{c}_{t_1}, t - t_1), \mathbf{c}_t\}$ ,  $\ddot{\mathbf{c}}_t = \max\{\iota(\mathbf{c}_{t_2}, t - t_2), \mathbf{c}_t\}$  where  $\mathbf{c}_t, \dot{\mathbf{c}}_t, \ddot{\mathbf{c}}_t \in \mathcal{C}(t)$  and  $\iota(\mathbf{c}_t, x) = \mathbf{c}_{t+x}$  where  $c_{t+x,k} = c_{t,k-x}$  if  $k - x \in [1, T]$ , and otherwise 0,  $\forall k \in [1, T]$ .

# Time Complexity

- The dynamic program has table size  $O(n^2|\Phi|^2|C|^2)$ .
- Constructing the solution from the sub-problems takes  $O(|\Phi||C|)$  steps.
- In total, the running time is  $O(n^2|\Phi|^3|C|^3) = O(n^8m^{3T})$ .
- When  $T$  is constant, our dynamic programming approach has polynomial running time.

# Outline

- Introduction
- Dynamic Programming Approach
- PTAS
  - PTAS with Resource Augmentation
  - Transform the solution to remove the extra machines
- Conclusion

# Ideas

- Compress the vectors by decreasing the number of possible distinct starting times of calibrations
  - By **delaying** the calibrations in the optimal solution

**Lemma 11.** *There exists a  $(1 + \epsilon)$  - approximation solution on  $(1 + \epsilon)m$  machines such that for any time slot  $t$ , the number of distinct starting times (and ending times) of the calibrations that cover time slot  $t$  is at most  $2 \lceil 1/\epsilon \rceil + 1$ , and there are at most  $m$  jobs scheduled at time slot  $t$ .*

- Maintain the schedule of the jobs as in the optimal schedule
- Only change the schedule of calibrations

# Divide Calibrations into Blocks

- We define **block** to be the set of consecutive calibrations satisfying
  - the largest difference of their starting times is less than  $T$
  - the set is maximal
- Partition the calibrations in the **optimal solution** into many disjoint blocks starting from the first calibration.
- Suppose a block contains  $l$  calibrations.
- Let  $\tau_i$  be the starting time of the  $i$ -th calibration in the block, we have  $\tau_1 \leq \tau_2 \leq \dots \leq \tau_l < \tau_1 + T$ .
- Also  $l \leq m$  because each of these calibrations covers time slot  $\tau_1 + T$ .

# Transformation in Blocks

Step 1. **(Partition)** We partition the calibrations in the block into  $\lceil 1/\epsilon \rceil$  **groups** such that each group contains at most  $\lceil \epsilon l \rceil$  consecutive calibrations.

- the partition is feasible as  $\lceil 1/\epsilon \rceil \times \lceil \epsilon l \rceil \geq l$
- the maximum calibration starting time in one group is no larger than the minimum calibration starting time in the next group.

Step 2. **(Delay)** For each group of calibrations, let  $\tau$  be the latest calibration starting time, then we delay the calibrations in this group so that they have identical starting time  $\tau$ .

# Transformation in Blocks

Step 3. **(Augment)** We add an extra group of  $\lceil \epsilon l \rceil$  calibrations once with identical starting time  $\tau_1$  on the extra  $\epsilon m$  machines.

Step 4. **(Transform)** For the calibrations that are delayed in each group, we reschedule the corresponding affected jobs on the extra machines, without changing the starting time of any job.

# Transformation in Blocks

# Vector Compression

- We define a **configuration** to be a pair of vectors  $\langle \alpha, \eta \rangle$  where  $\alpha = \langle \alpha_1, \alpha_2, \dots, \alpha_h \rangle, \eta = \langle \eta_1, \eta_2, \dots, \eta_h \rangle$  and for each  $i \in [1, h], \alpha_i \in \{NUL\} \cup \Psi$  indicates the starting time of a calibration,  $\eta_i \in [0, m']$  indicates the number of the calibrations that share the same starting time  $\alpha_i$ .
- We define  $A = \{ \langle \alpha_1, \alpha_2, \dots, \alpha_h \rangle \mid \alpha_i \in \{NUL\} \cup \Psi, \forall i \in [1, h] \}$  to be the set of all possible vectors  $\alpha$ . Given time slot  $t$ , we define  $A(t) = \{ \langle \alpha_1, \alpha_2, \dots, \alpha_h \rangle \mid \alpha_i \in \{NUL\} \cup (\Psi \cap [t - T, t)), \forall i \in [1, h] \}$
- Let  $B = \{ \eta \mid \sum_{i=1}^h \eta_i \leq m', \eta_i \in [0, m'], \forall i \in [1, h] \}$  be the set of all possible vectors  $\eta$ .

# Dynamic Programming States

**Defination 13.** We define  $f^\#(j, t_1, t_2, q, \langle \check{\alpha}, \check{\eta} \rangle, \langle \hat{\alpha}, \hat{\eta} \rangle)$  to be the minimum number of extra necessary calibrations to schedule jobs  $J(j, t_1, t_2)$  on  $m'$  machines where  $j \in J, t_1 \in \Phi, t_2 \in \Phi, q \in [0, m], \check{\alpha} \in A(t_1), \hat{\alpha} \in A(t_2), \check{\eta} \in B, \hat{\eta} \in B$  on the condition that

- jobs in  $J(j, t_1, t_2)$  are only scheduled during time interval  $(t_1, t_2]$ .
- calibrations indicated by configurations  $\langle \check{\alpha}, \check{\eta} \rangle$  and  $\langle \hat{\alpha}, \hat{\eta} \rangle$  have already been selected to be assigned to machines.
- $q$  other jobs (not from  $J(j, t_1, t_2)$ ) have already been assigned at time slot  $t_2$ .
- there are at most  $m$  jobs scheduled at any time slot.

# Dynamic Programming Transitions

$$f^\#(j, t_1, t_2, q, \langle \check{\alpha}, \check{\eta} \rangle, \langle \hat{\alpha}, \hat{\eta} \rangle) =$$

$$\min_{t \in \Phi(j) \cap (t_1, t_2]} \left\{ \begin{array}{ll} \infty & , \text{if } t = t_2, q = m \\ f^\#(j - 1, t_1, t_2, q + 1, \langle \check{\alpha}, \check{\eta} \rangle, \langle \hat{\alpha}, \hat{\eta} \rangle) & , \text{if } t = t_2, 0 < q < m \\ \min_{\text{cond.}} \left( \sum_{i=0}^h \eta_i \right) & , \text{if } t < t_2 \text{ or } q = 0 \\ + f^\#(j - 1, t_1, t, 1, \langle \check{\alpha}, \check{\eta} \rangle, \langle \check{\alpha}, \check{\eta} \rangle) & \\ + f^\#(j - 1, t, t_2, q, \langle \check{\alpha}, \check{\eta} \rangle, \langle \hat{\alpha}, \hat{\eta} \rangle) & \end{array} \right.$$

where *cond.* stands for  $\langle \check{\alpha}, \check{\eta} \rangle = \langle \alpha, \eta \rangle \cup_t \langle \hat{\alpha}, \hat{\eta} \rangle$ ,  $\langle \check{\alpha}, \check{\eta} \rangle = \langle \alpha, \eta \rangle \cup_t \langle \check{\alpha}, \check{\eta} \rangle$  where  $\alpha, \check{\alpha}, \check{\alpha} \in \mathcal{A}(t)$  and  $\eta, \check{\eta}, \check{\eta} \in \mathcal{B}$ .

# Time Complexity

- The modified dynamic program has table size  $O(n^2|\Phi|^2(|A||B|)^2)$ .
- Constructing the solution from the sub-problems takes  $O(|\Phi||A||B|)$  steps.
- In total the time complexity is

$$O(n^2|\Phi|^3(|A||B|)^3) = O(n^2|\Phi|^3n^{3h}|\Psi|^{3h}) = O(n^{17+18\lceil\frac{1}{\epsilon}\rceil})$$

# Remove the extra machines

- We consider the earliest time slot  $t$  such that more than  $m$  machines are calibrated at time slot  $t$ .
- Case 1) If no such time slot  $t$  exists, we then assign the calibrations to  $m$  machines via Round-Robin method, and obtain a feasible solution on  $m$  machines.
- Case 2) Otherwise, there must be some calibration starting at time  $t - 1$ , we then delay this calibration by one more time slot. Note that jobs are still feasible since there are at most  $m$  jobs scheduled at time slot  $t$ . repeat the above process until Case 1) occurs.
